• CP violation in the charm sector had been investigated for a number of modes in the Belle Experiment. A few recent results are

$$\begin{array}{l} {\cal A}_{CP}(D^0 \to \pi^0 \pi^0) = (-0.03 \pm 0.64 \pm 0.10)\% \\ {\cal A}_{CP}(D^0 \to K_s^0 \pi^0) = (-0.21 \pm 0.16 \pm 0.07)\% \\ (\text{N.K.Nisar et al. arXiv:1404.1266[hep-ex] 2014}) \end{array}$$

$$A_{CP}(D^+ \to K_s^0 K^+) = (-0.25 \pm 0.28 \pm 0.14)\%$$

(B.R.Ko et al. arXiv:1212.6112 [hep-ex] 2013)

$$\begin{aligned} &A_{CP}(D^+ \to K_s^0 \pi^+) = (-0.363 \pm 0.094 \pm 0.067)\% \\ & (\text{B.R.Ko et al. arXiv:1001.3202[hep-ex] 2012}) \end{aligned}$$

$$A_{CP}(D^+ \rightarrow \phi \pi^+) = (+0.51 \pm 0.28 \pm 0.05)\%$$

(M.Staric et al. arXiv:1110.0694 [hep-ex] 2011)

- The paper by Gino Isidori and Jernej F. Kamenik (2012)(PhysRevLett.109.171801) using models beyond SM, predicts sizeable CP Asymmetry in modes of the kind D⁰ → Vγ where V is a vector particle, upto several percent.
- Thus this can be an important search for physics beyond the standard model. We intend to search for CP violation in the mode $D^0 \rightarrow \phi \gamma$

Why study $D^0 \rightarrow \phi \pi^0$?

- The modes $D^0 \rightarrow \phi \pi^0$ and $D^0 \rightarrow \phi \eta$ are important backgrounds for our signal mode $D^0 \rightarrow \phi \gamma$ as both the π^0 and η decay into two photons and if one of the photons is not reconstructed, it would resemble our signal.
- The branching fractions of the modes are (PDG, PR D86, 010001 (2012))

$$\begin{split} \mathcal{B}(D^0 \to \phi \pi^0, \, \phi \to K^+ K^-) &= (6.4 \pm \, 0.4) \times 10^{-4} \\ \mathcal{B}(D^0 \to \phi \eta) &= (1.4 \pm \, 0.5) \times 10^{-4} \\ \mathcal{B}(D^0 \to \phi \gamma) &= (2.7 \pm \, 0.35) \times 10^{-5} \end{split}$$

• We study the mode $D^0 \rightarrow \phi \pi^0$ because of its relatively higher branching fraction (more than 20 times the signal $D^0 \rightarrow \phi \gamma$) and because it will familiarize us with the fitting and extraction procedure for A_{CP}

Figure : Signal Process Diagrams for $D^0 \to \phi \pi^0$ and $\overline{D^0} \to \phi \pi^0$

Cuts Applied ($D \rightarrow \phi \pi^0$)

- $|dr|_{K^{\pm},\pi_s} < 1.0~\mathrm{cm}$
- $|dz|_{K^{\pm},\pi_s} < 3.0 \ \mathrm{cm}$
- $\mathcal{R}_{\mathcal{K}^{\pm}}$ (Kaon Likelyhood) > 0.1
- \mathcal{R}_{π_s} (Kaon Likelyhood) < 0.9
- 1.01 GeV $< M_{\phi} <$ 1.03 GeV
- $E_{\gamma} > 50 MeV$ (Barrel)
- $E_{\gamma} > 100 MeV$ (Endcap)
- 119 MeV $< M_{\pi^0} <$ 151 MeV
- $P_{D^*}^* > 2.5 GeV$ (optimized)
- $P_{\pi^0} > 380 MeV$ (optimized)
- 1.83 GeV $< M_{D^0} < 1.89$ GeV (optimized)
- 140 MeV $< \Delta M <$ 160 MeV

Figure : 2-D cut optimization

Figure : ΔM distribution.

- Since the $P_{D^*}^* P_{\pi^0}$ variables are correlated, a 2-D optimization , varying each cut independently, is performed.
- The optimizations are performed by minimizing the figure of merit,

Figure : $\cos\theta_{\text{hel}}$ distribution. 5/18

How we measure CP asymmetry, A_{CP}

• A_{rec} is defined in terms of signal yield (N_{rec})

$$A_{rec} = \frac{N_{rec}^{D^{*+} \to D^0 \pi_s^+} - N_{rec}^{D^{*-} \to \overline{D^0} \pi_s^-}}{N_{rec}^{D^{*+} \to D^0 \pi_s^+} + N_{rec}^{D^{*-} \to \overline{D^0} \pi_s^-}}$$

 A_{rec} is the sum of three terms. $A_{rec} = A_{cp} + A_{FB} + A_{\epsilon}^{\pi_s}$

- It has been demonstrated from previous CP asymmetry studies that the pion detection efficiency asymmetry $A_{\epsilon}^{\pi_s} = +0.11\%$
- Since A_{FB} is an odd function of cos(θ^{*}_{D*}), we divide the data in bins of cos(θ^{*}_{D*}) and extract A_{cp} and A_{FB} from it by adding and subtracting bins at ±cos(θ^{*}_{D*})

$$A_{CP} = \frac{A_{rec}^{cor}(\cos(\theta_{D*}^*) + A_{rec}^{cor}(-\cos(\theta_{D*}^*))}{2} \text{ and }$$
$$A_{FB} = \frac{A_{rec}^{cor}(\cos(\theta_{D*}^*) - A_{rec}^{cor}(-\cos(\theta_{D*}^*)))}{2}$$

Full $\Upsilon(4S)$ MC ΔM Fit: Shift in $\cos \theta_{\text{hel}}$ distribution

Figure : Simultaneous fit of the Full $\Upsilon(4S)$ generic MC (711 fb^{-1})

For the Helicity component, the signal shape is modeled by an $(x - a)^2$ function. The fitted value obtained for the helicity shift parameter is $a_{\text{shift}} = 0.0019 \pm 0.0026$

Full $\Upsilon(4S)$ Data 2D Fit: Shift in $\cos \theta_{\text{hel}}$ distribution

Figure : Simultaneous 2-D fit of the Full $\Upsilon(4S)$ Data (711 fb^{-1})

э

8/18

The fitted value obtained for the helicity shift parameter is $a_{\rm shift} = -0.05199 \pm 0.0026 \ (\sim 20\sigma effect)$

Sample	A_{CP}^{uncorr} (1-D Fit) %	A ^{uncorr} (2-D Fit) %
MC 0	-0.09 ± 0.84	$+0.16\pm0.83$
MC 1	-0.82 ± 0.85	-0.96 ± 0.84
MC 2	$+0.83 \pm 0.84$	$+1.04\pm0.83$
MC 3	$+1.63\pm$ 0.84	$+1.50\pm0.83$
MC 4	$-0.29\pm$ 0.83	-0.25 ± 0.82
MC 5	-0.28 ± 0.84	-0.22 ± 0.83
Data	-0.047 ± 0.86	-0.60 ± 0.81

Since we do not correct for the slow Pion detection efficiency asymmetry, we measure $A_{CP}^{uncorrected} = A_{CP} + A_{\epsilon}^{\pi_s}$

$D^0 \rightarrow \phi \gamma$ Study : Efficiency of the Extended π^0 Veto

- The candidate photon in in our main channel $D \rightarrow \phi \gamma$ is clubbed up with all other photons in the event and a probability is assigned for each combination on whether they come from a decayed π^0 .
- We have tried to improve the Vetoing efficiency by including in our list of photons in the given event, photons that have converted into an e⁺e⁻

Summary of cuts

Variable	$Cut-\Upsilon(4S)$	Eff. (%) Loss	$Cut-\Upsilon(5S)$	Eff.(%) Loss

$D^0 o \phi \gamma$: Backgrounds, 2-D optimization

Helicity Distribution

2-D Optimization for Y(4S)

Comparison of different fitting schemes

Table : Comparison of fitting results

Fit type	A _{raw} measured %
ΔM -cos θ_{hel} 2-D Fit	-4.5 ± 8.5
M_D -cos θ_{hel} 2-D Fit	-2.7 ± 7.5
3-D Fit	0.2 ± 6.9

- For the ΔM -cos θ_{hel} fit, we use an optimized M_D signal window (1.84 1.89 GeV), and for the M_D -cos θ_{hel} fit, we use an optimized ΔM signal window (142 148 MeV)
- The 3-D fit has the smallest uncertainty in A_{CP}

Projections of the 3-D fit to the variables ΔM , M_D and $\cos \theta_{hel}$

1	-4.3 ± 6.4
2	-5.2 ± 6.2
3	$+2.3\pm6.9$
4	-1.2 ± 7.0
5	-3.6 ± 6.3

The method of reweighting: A_{Raw} for $D \to K_S \pi^0$

- Since we do not expect large statistics for the main mode $D \rightarrow \phi \gamma$, the method of binning in the D^* production direction to correct for A_{FB} is not viable.
- Instead, we use a high statistics mode like $D \rightarrow K_S \pi^0$ to estimate A_{FB} bin by bin, and we use these values to appropriately assign weights to our signal mode, during the simultaneous fitting, in order to correct for A_{FB} .

Table :	Comparison	of total	A_{CP}	measurements for	or the	mode <i>L</i>	$D \to K_S \pi^0$
---------	------------	----------	----------	------------------	--------	---------------	-------------------

イロン 不留 とくほど 不良とう 語

- Extensive Monte Carlo studies have been performed on the sources of backgrounds and the A_{CP} estimation procedure. We have also estimated the sensitivity of our final A_{CP} measurement using various streams of generic MC.
- The studies performed are under collaboration wide review, and once the scrutiny is completed, we expect to look at *A_{CP}* in real data.

THANK YOU!
